

The Latest Strategies for Managing Asian Citrus Psyllid in your Groves

Beth Grafton-Cardwell

Dept of Entomology, UC Riverside

Director of Lindcove Research and Extension Center

Huanglongbing disease (HLB)

Bacterial disease:

Candidatus Liberibacter asiaticus Clas

As the disease progresses:

- *Roots decline
- Leaves become yellow
- Foliage becomes thin
- Fruit drops off easily
- Fruit is smaller
- Juice is bitter
- Tree death (there is no cure)

Why is this disease so quick to spread and so hard to detect?

The nymphs hatch and immediately pick up the bacterium and spread it when they molt and fly away 4-6 weeks later.

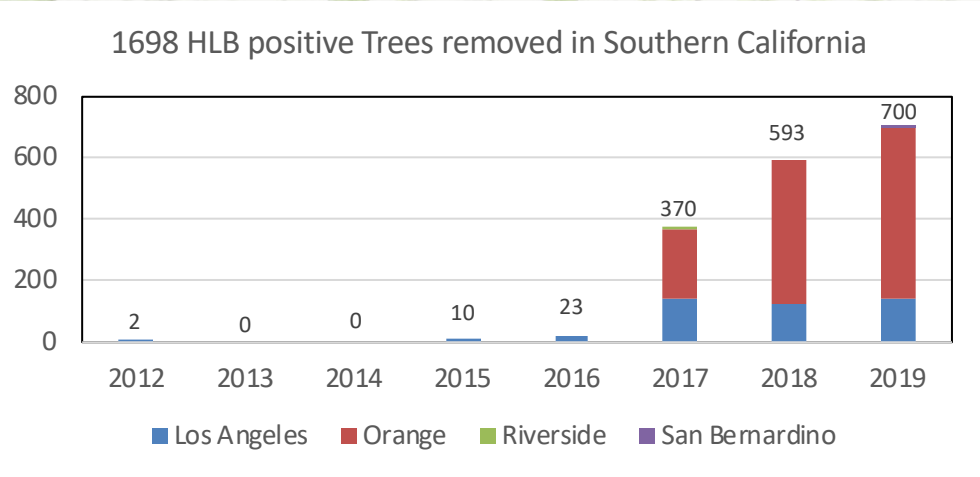

The eggs are laid on new flush next to the where the psyllid injects the bacterium.

When leaves are sampled, they must have the bacteria for PCR to detect it. It takes 9 months to 2 years for the bacteria to spread throughout the tree for sampling to pick the right leaf.

HLB Infected Tree Removal Residential areas of Los Angeles, Orange, Riverside and San Bernardino

The California Situation

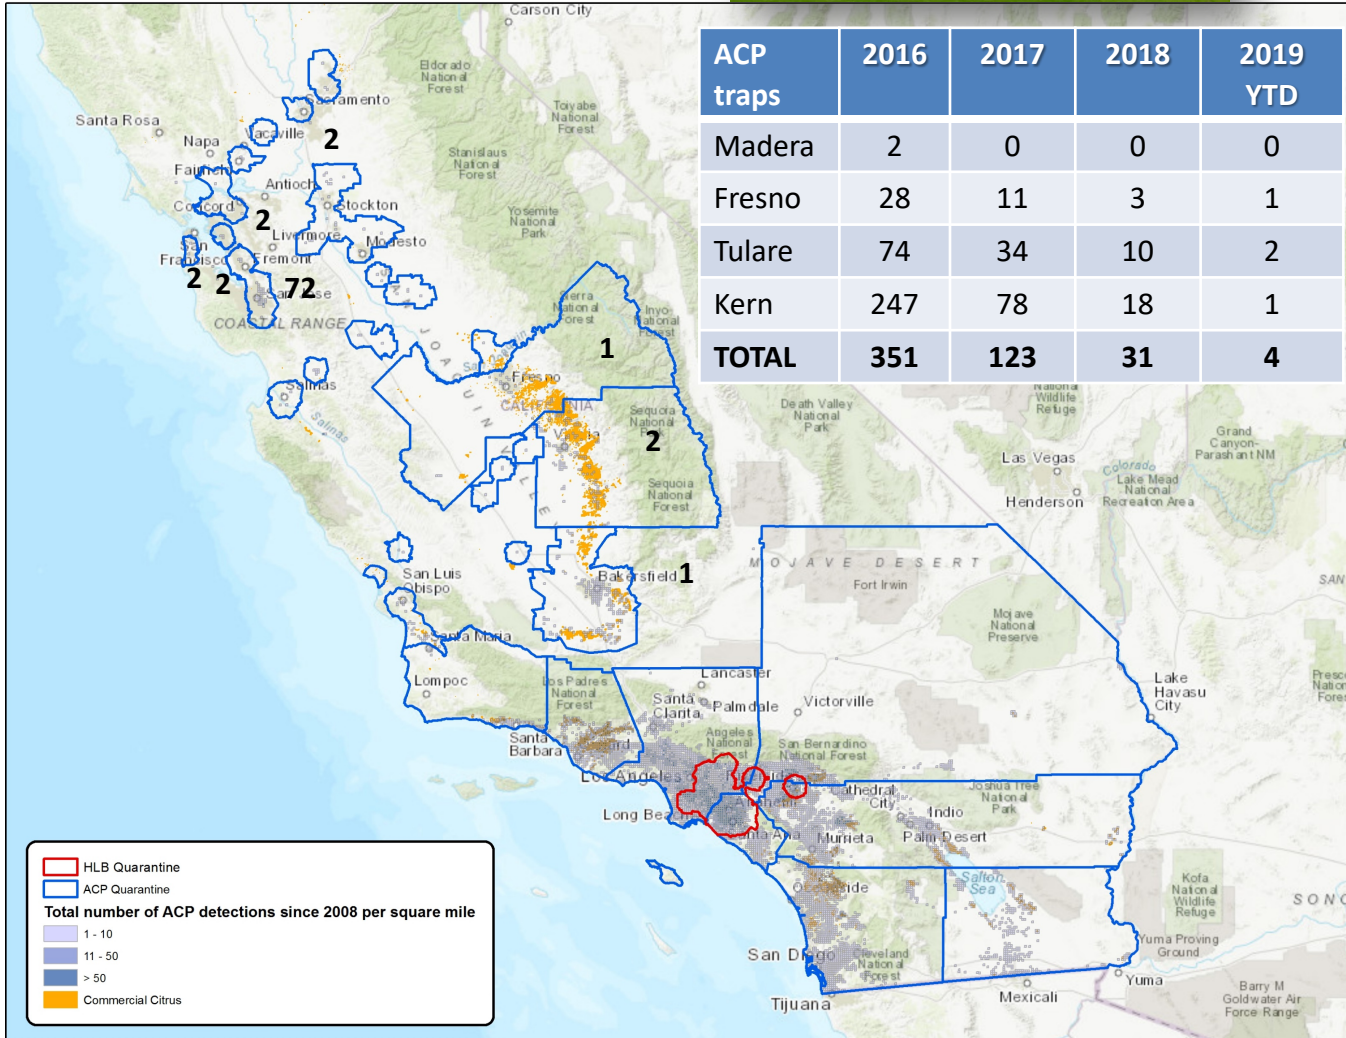

Goal: reduce psyllids to reduce the spread of disease

<http://ucanr.edu/sites/ACP/>

Central/Northern CA:
Eradicative/ Coordinated
Treatments – treat find sites with two insecticides
Commercial citrus: 800 meters or coordinated treatments
Urban: 400 meters

Southern California:
Area-wide treatment program
Commercial citrus: Growers treat together over a 2-3 week window (fall and winter) coordinated by PMAs, pest control districts, or task forces
Urban: parasites released

Ventura 2019

- **Psyllids are still out there**
- **Treatments + weather are helping to keep them low**
- **Don't stop treating, but consider additional perimeter treatments in the fall**
- **The fewer the psyllids the slower the spread of the disease**

Scouting psyllid nymphs is essential

The yellow sticky traps are not very attractive

Tap sampling doesn't reveal many adults

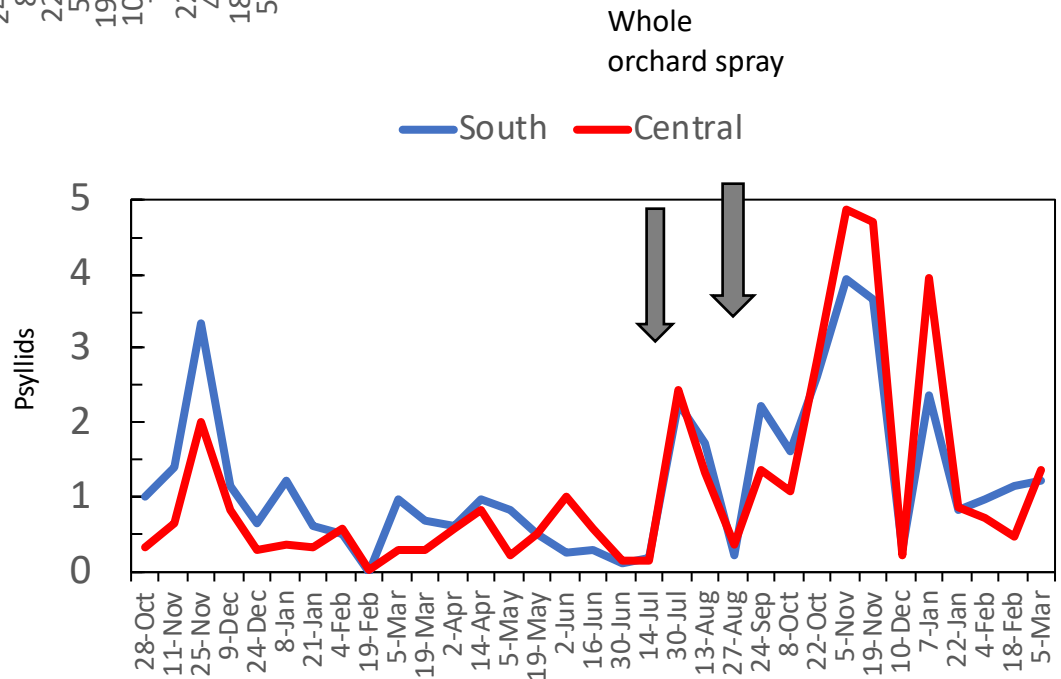

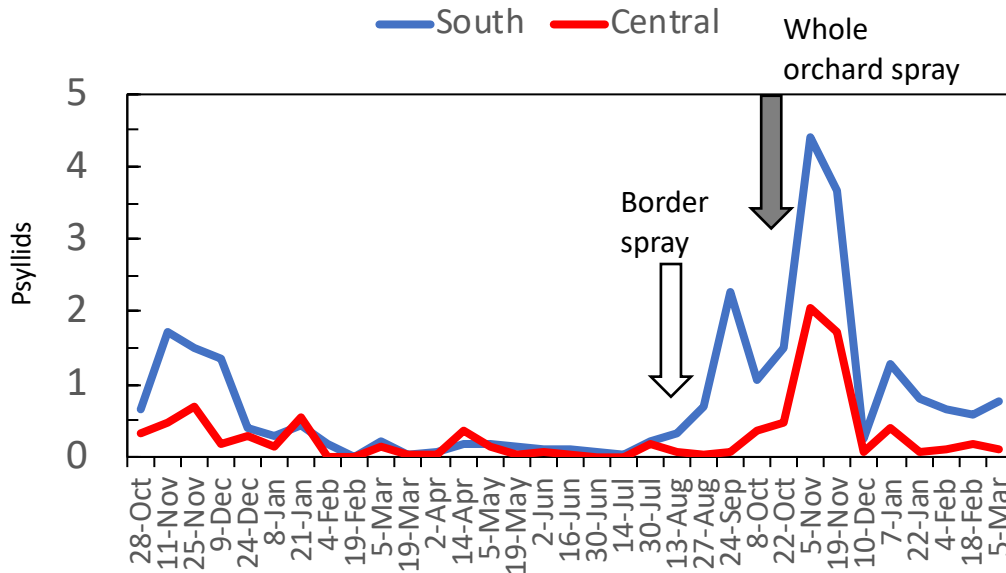

Examining suitable flush for psyllid **nymphs** is much better

Every 2 weeks – 10 trees on each border and one row in the center

Threshold for treatment is 0.5 nymphs per flush (5 psyllids/10 trees)

What does the preference for edges mean for managing ACP?

Nymphs per Flush

- Low levels ACP stay on the border
- High levels, small or young blocks ACP are found throughout
- Treat borders whenever psyllids start to increase (don't wait for the areawide scheduled treatment)

Young trees/replants – they are very attractive to psyllids

- Additional insecticides – entire block
- Mesh tree covers
- Repellent sprays
- Reflective mulches

Citrus Under Protective Screen (CUPS) for California?

Windbreaks, barriers, etc. to block psyllid flight into the orchard

- Windbreak – living barrier
- Fence (screen mesh) – artificial barrier
- Repellents (Celite and kaolin clay)
- Trap crop (for example Murraya)?

Not every technique will work in every orchard, and good efficacy may require **'stacking'** techniques

Growers should learn what's new, be creative and figure out what works for their situation.

- HLB is moving spreading in Southern California.
- What happens when HLB is found in or near a commercial orchard?
- CDFA and the grower each have a role in responding

• CLas (HLB) tree or psyllid nymph

CDFA Mandatory response

- 400 meter testing and treatment
- 5 mile zone that bulk citrus needs extra mitigations to move it out of the area

CDFA
400 m response

Riverside County

Source

HLB+ tree

Mandatory Protocols For HLB

HLB+ ACP nymph

Mandatory actions by grower

- Treat the tree with insecticide within 72 hours
- Remove the tree and destroy the roots 48 h after REI has ended
- Treat all citrus within 400 meters of the disease tree within 7 days
 - 1 foliar if in areawide
 - 2 treatments if no areawide treatment

Mandatory actions by grower

- Treat the tree with insecticide within 72 hours
- Remove the tree and destroy the roots 48 h after REI has ended
- Treat all citrus within 400 meters of the disease tree within 7 days
 - 1 foliar if in areawide
 - 2 treatments if no areawide treatment

Actions by CDFA

- Collect leaf samples from perimeter trees in the orchard and neighboring orchards within 400 m and test for HLB
- **Establish a 5 mile quarantine**
- Resample once a year

Actions by CDFA

- Collect leaf samples from perimeter trees in the orchard and neighboring orchards within 400 m and test for HLB
- ***No 5 mile quarantine***
- Resample once a year

HLB App for Citrus Growers

ucanr.edu/hlbgrowerapp

HLB App for Citrus Growers: How close is HLB to my acreage?
Click the map or use the Search Bar to specify your location.

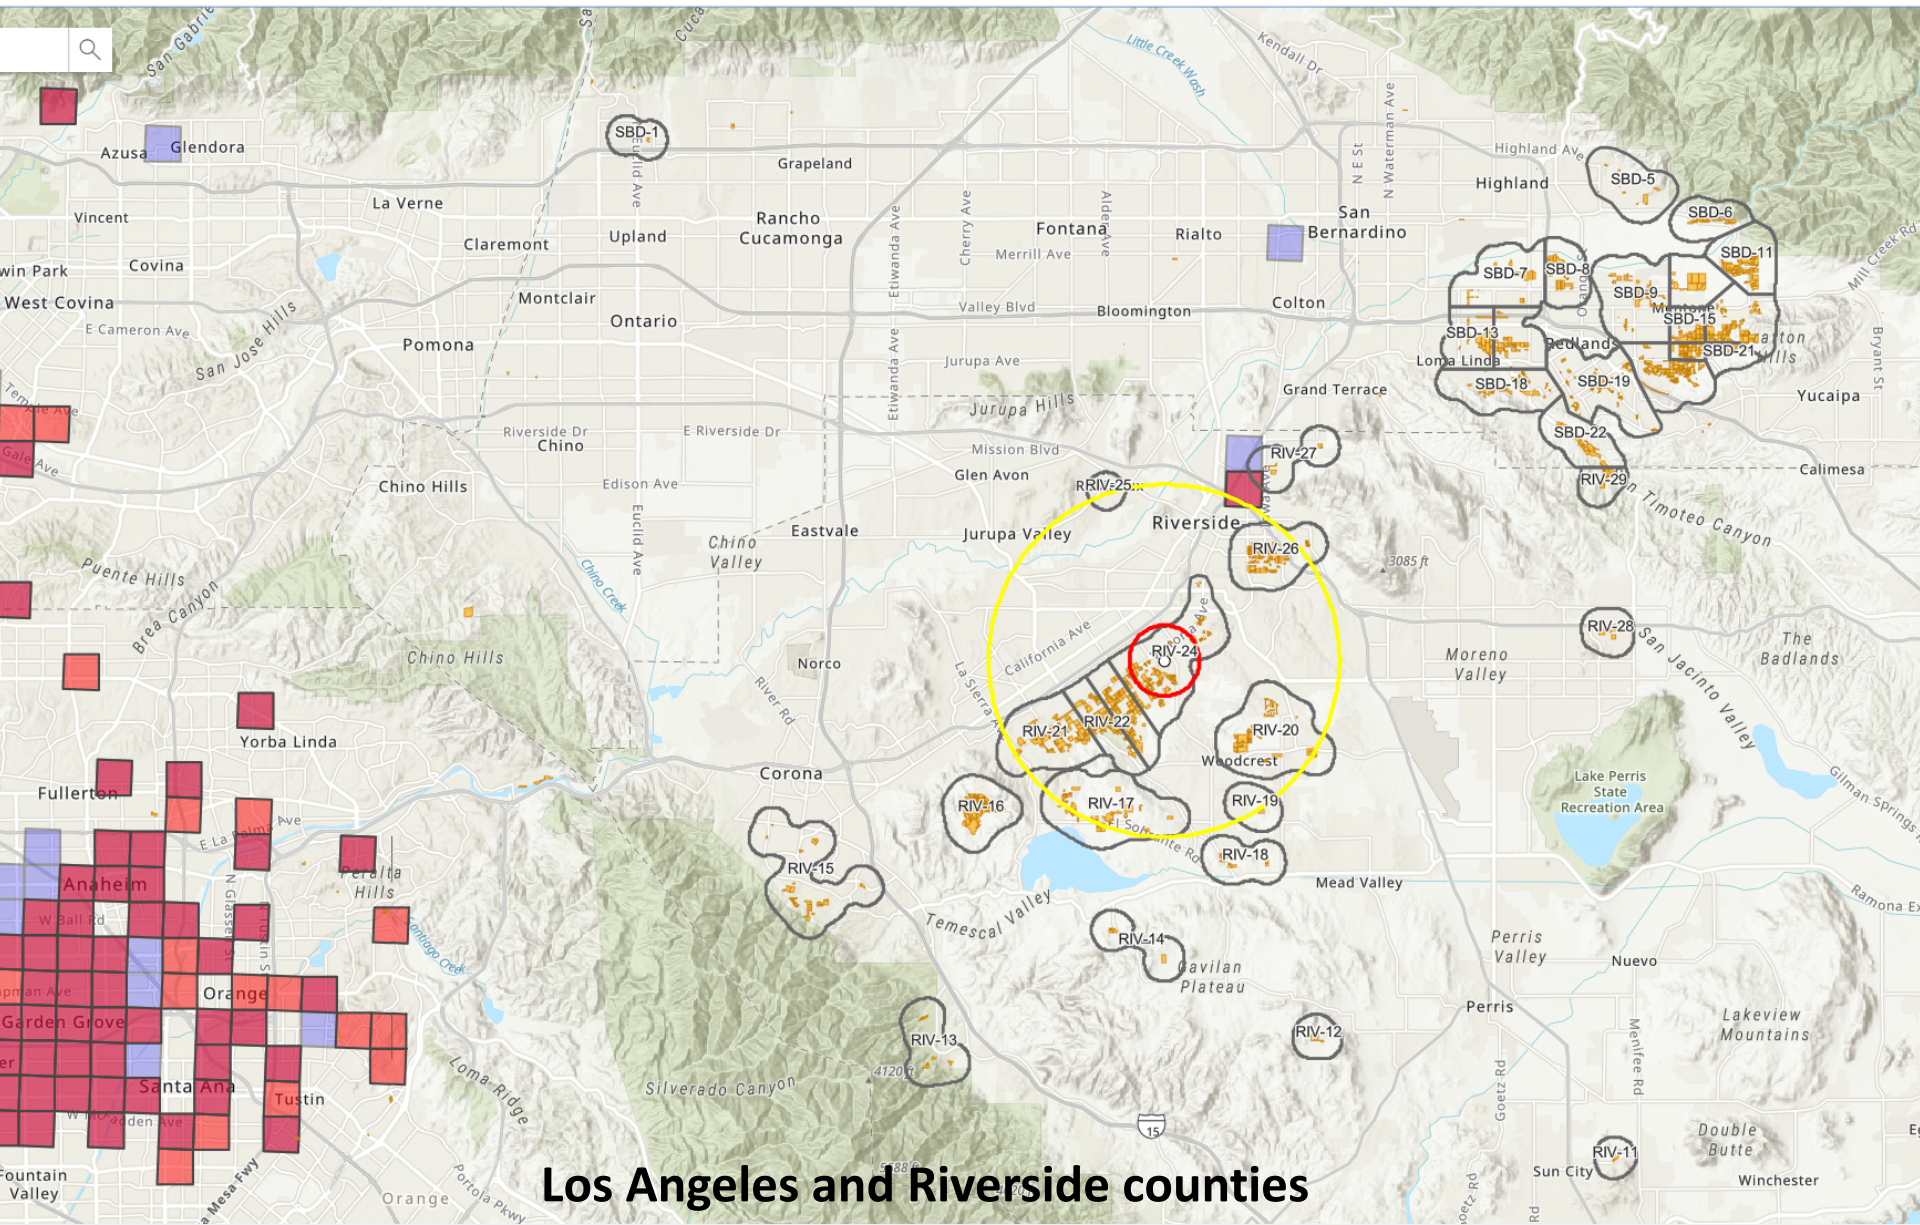

Use your phone to open this UC ANR app and take a quick look at how close HLB+ trees are to your orchard.

To best understand how to protect your citrus from HLB, follow the link on the other side of this card to the [Voluntary Grower Response Plan](#) that provides the latest recommendations for protecting citrus from HLB.

Psyllid management areas, citrus layer, HLB+ tree removals (red), HLB+ psyllids (purple)

5 miles of an HLB detection in a psyllid or tree. The red ring shows < 1 mile and the yellow ring shows 1-5 miles distance from infection. Your trees may be infected with HLB. Control and regularly test the perimeter of your orchard for HLB. See the [voluntary grower response plan](#) for more details.

Los Angeles and Riverside counties

How does the response change as you get closer to HLB?

Scenarios 1 (outside the 5 mile HLB Q zone)

- Awareness
- Scouting for ACP
- Control of ACP
- Young tree/Replant
- Barriers/Repellents
- Visual Survey for HLB
- HLB Detection
- Tree Health

Scenarios 2-4 (inside the 5 mile HLB Q zone)

- Intensify types and number of treatments for ACP
- Install barriers/repellents
- Increase surveillance for HLB
- Comply with treatment and tree removal of HLB+ trees

What about early detection techniques (EDTs)?

- The **metabolism** of sick trees changes and that can be measured (Slupsky, UCD)
- Sick trees produce **proteins** (small RNAs) to protect themselves (Jin, UCR)
- The bacteria produce **proteins** that circulate and can be measured (Ma, UCR)
- Sick trees have different **microbes** living on them (Leveau and Roper, UCR)
- Sick trees emit **VOCs** (volatile organic compounds) that can be measured with a gas chromatograph (Davis, UCD)
- **Canines can detect the bacteria and alert (sit) by individual trees (Gottwald, UFL)**

EDTs are not included in the voluntary grower response plan because they are not readily available - growers should watch for updates

F1K9

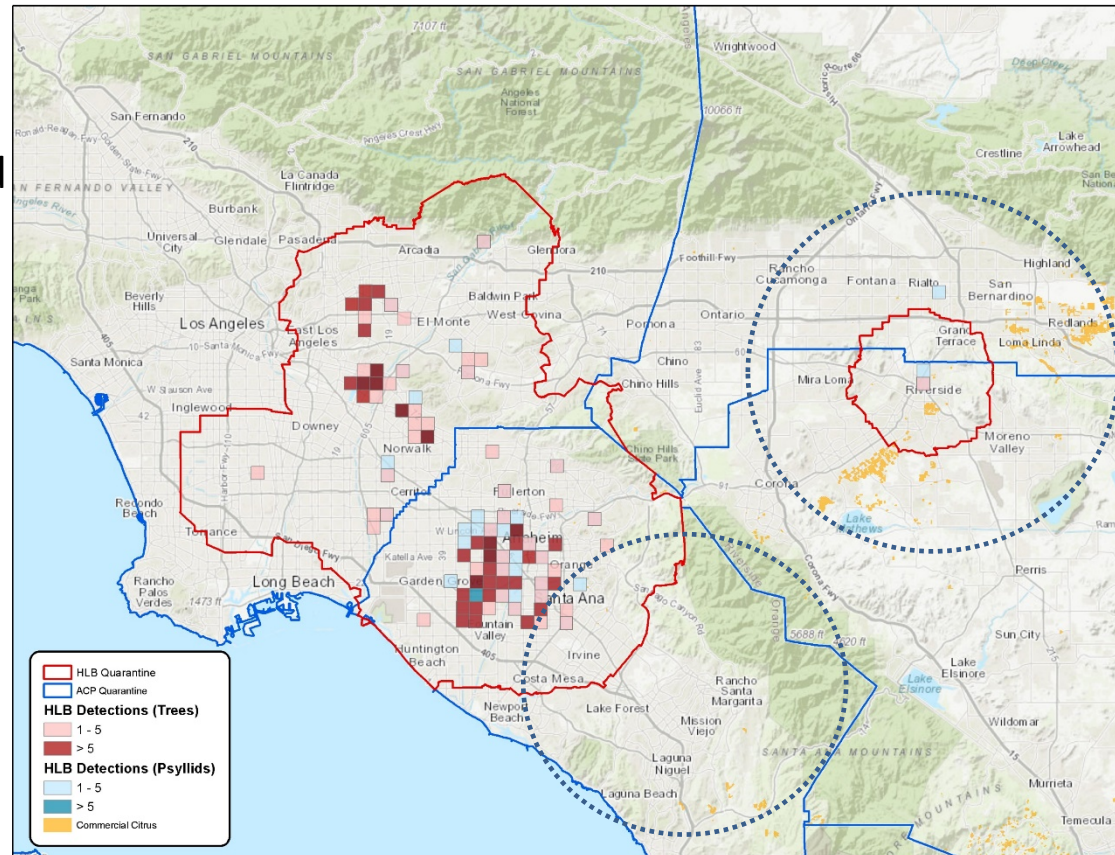

What about bactericides?

Bactericides help prevent bacteria from establishing in the citrus leaf.

However, they break down fast so they must be applied frequently.

- 6 treatments (4 spring flush/2 fall flush) minimum 21 days apart
- Rotate between **FireWall 50 WP** (streptomycin) and **FireLine 17 WP** (oxytetracycline) + adjuvant for resistance management
- Limited use in commercial citrus
 - ❑ HLB Quarantine
 - ❑ 15 miles around an HLB Q
 - ❑ 15 miles around a PCR+ psyllid
- They could be applied as a border treatment as this is where the infections usually start

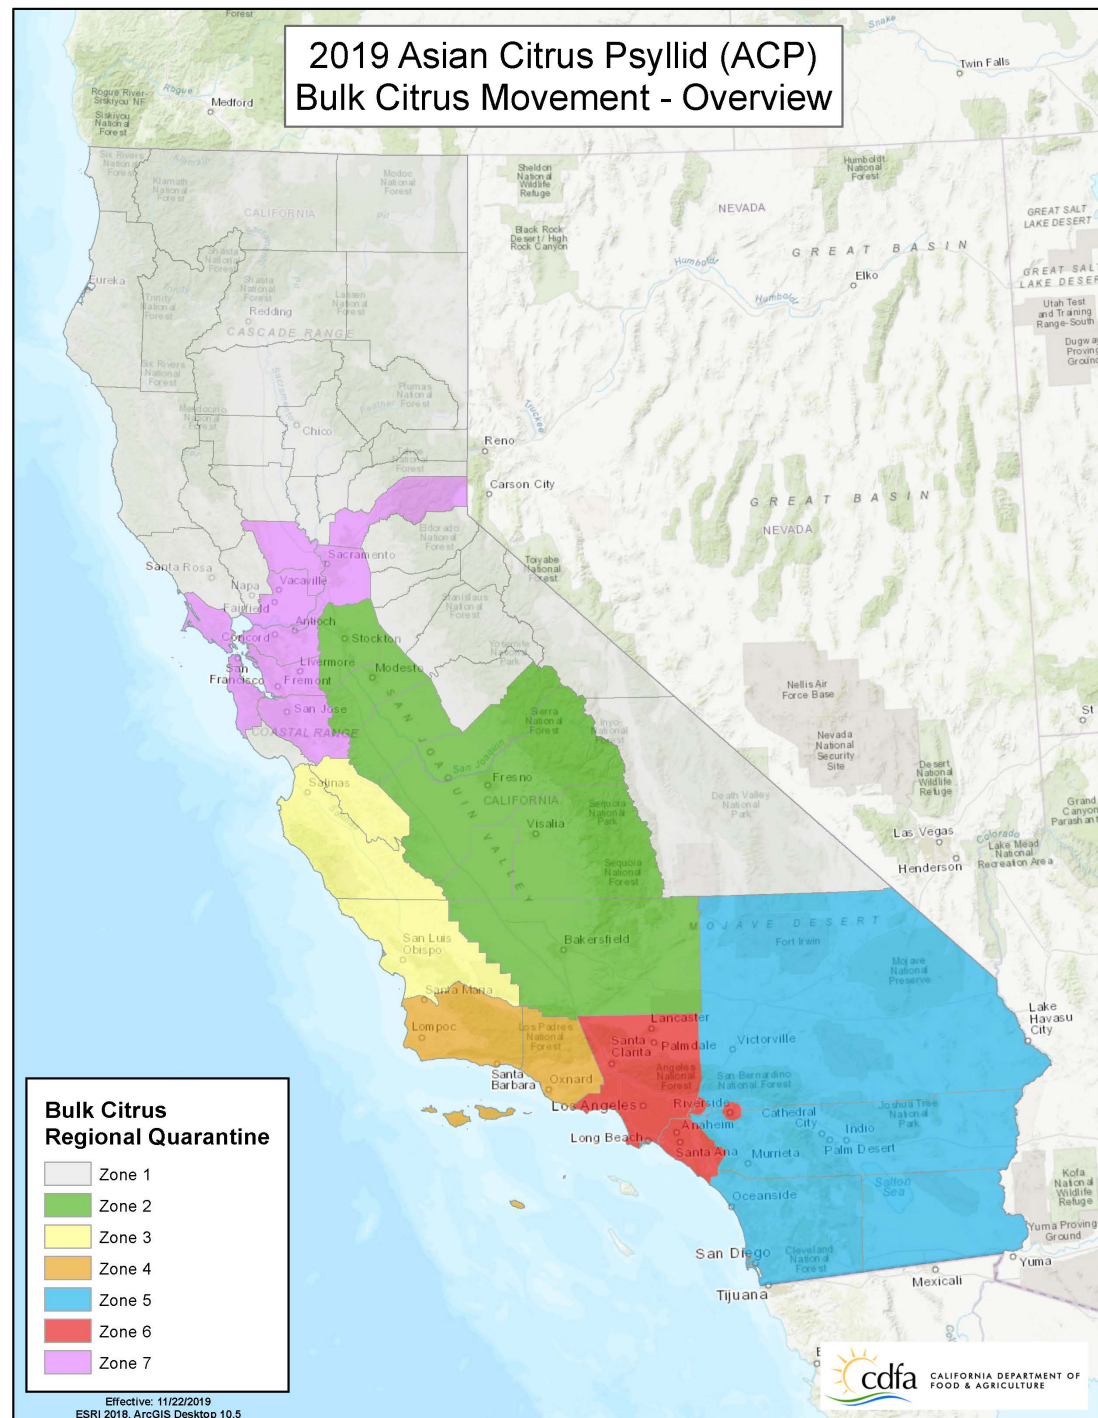

Bactericides are not included in the voluntary grower response plan because we do not know how effectively they will prevent HLB infections - growers should watch for updates

Bulk Citrus Movement

between zones requires a mitigation to make sure there are no psyllids riding on the fruit.

TWO mitigations are required for shipping out of zone 6 where HLB has been found

Bulk Citrus Movement in HLB Q areas requires TWO mitigations

1. spray the orchard with a pesticide prior to harvest (Actara, pyrethroids, Lannate)
2. Mechanically clean or wash the fruit after harvest
3. Evergreen pressurized spray

Fumigation with Ethyl Formate gas – 2020

2019 Trial (Walse, Gautam, Mitcham)

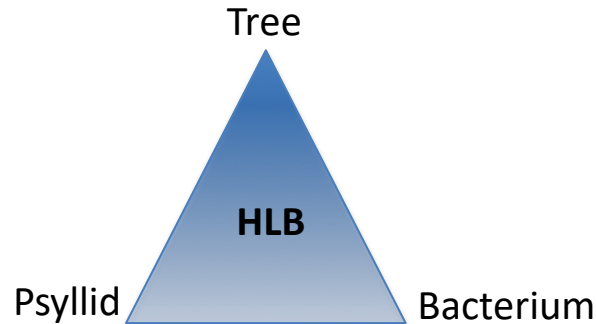

1 hour exposure with Ethyl formate (250 g/m^3)

72 cages of psyllids, replicated trial – no survival of the 2,194 psyllids tested

Scientists are studying every conceivable way to stop this disease

- **Early detection techniques** to find and destroy diseased trees
- Improved **Psyllid traps** – attract and kill
- **Bactericide** treatments and new ways to kill the bacterium
- **Resistant** rootstocks and scions (traditional breeding and gene editing)
- Genetically engineer an **altered citrus tristeza virus** to introduce **anti-HLB genes** into plants
- Inserting a **Bt toxin gene** or **psyllid virus** into citrus or a trap crop to kill the psyllid
- Genetically engineer the psyllid so it can't vector the disease and release the **altered psyllid** as a sterile insect to replace the wild ones (GE)

Controlling psyllid gut cell death to prevent Huanglongbing

Research by Dr. Michelle Heck, USDA-Boyce Thompson Institute
Article written by Elizabeth Gratton-Carver, Peggy G. LeMay, & Luana Steiner. Revised September 13, 2015.
<http://ucanr.edu/sites/scienceforcitrushealth/>

What is the technique?
Plant pathogens can have devastating effects on plant health and can severely limit food production in agricultural crops. In the case of the devastating disease, huanglongbing (HLB), the tiny Asian citrus psyllid is the vector that picks up the bacterial pathogen (*Candidatus Liberibacter asiaticus* - CLAs) and transmits it to the next citrus tree during feeding. HLB is spread easily by psyllids. The focus of this research is determining how to control the psyllid when it feeds on citrus trees. Understanding how and why programmed cell death response may benefit the bacteria by allowing the bacteria to exit the gut and then enter the insect's blood stream (hemolymph), ultimately reaching the insect's mouthparts so that CLAs can be passed on when the psyllid feeds on a new host plant.

How is this research being done?
The first step is to identify the genes that are involved in the gut cell death response. Researchers are using genetic tools to study the function of these genes and to determine if they can be manipulated to reduce the damage caused by the bacteria.

Canines can detect trees infected with the bacterium that causes huanglongbing

Research by Dr. Tim Gottwald, USDA-ARS, Fort Pierce, Florida
Article written by Tim Gottwald, Holly Deniston-Sheets and Beth Gratton-Carver. Revised June 11, 2019. <http://ucanr.edu/sites/scienceforcitrushealth/>

What is the technique?
Canines have a highly sensitive scent detection capability that is significantly better (parts per trillion) than most laboratory instruments and they can be trained to "alert" (either sit or lay) when they detect specific "smells" (known as scent signatures). Most people are familiar with their ability to detect bombs, drugs, and plant material at airports. However, canines are also used to detect human pests, such as bed bugs, and agricultural pests, such as stink bugs, date palm weevils and imported fire ants. With regard to agricultural pathogens, canines have been shown to detect with greater than 98% accuracy the fungal pathogen that causes laurel wilt disease in avocado, the bacterium that causes citrus canker disease in citrus, and plum pox virus in peach orchards.

Researchers have been training and evaluating the efficacy of canines for detecting "*Candidatus Liberibacter asiaticus*" (CLAs), the bacterium that causes huanglongbing (HLB), for 5 years in Florida, and CLAs detection efforts with canines have recently begun in California. Dogs have been trained in both the laboratory environment and in the field. Researchers have demonstrated that well-trained canines can detect CLAs over 95% of the time in commercial trees and over 92% of the time in residential trees. Researchers did not observe any differences in canine performance between citrus species and varieties. The training that the canines receive is very specific to CLAs. When they are taken into citrus orchards infected with *Citrus tristeza* virus, viroids, the fungal pathogen *Phytophthora*, or the bacterium that causes citrus stubborn, the CLAs-trained canines do not respond to these diseases.

as 2 weeks after CLAs-infected psyllids fed on the trees. In contrast, it can take 1-2 years for CLAs to distribute itself in a mature citrus tree sufficiently for the bacterium to be present in sampled the leaves, which are then tested and shown to be infected using laboratory techniques, such as Polymerase Chain Reaction (PCR). Using canines to detect early infections could significantly help reduce disease spread in California, where HLB is currently limited to southern areas of the state and identify areas where increased psyllid control measures are needed.

Who is working on the project?
Dr. Tim Gottwald, Research Leader and Epidemiologist at the USDA, U.S. Horticultural Research Laboratory in Fort Pierce, Florida, and additional collaborators with FKH laboratories, USDA, North Carolina State University, Texas A&M University and the California Department of Food and Agriculture.

What are the challenges and opportunities?
The volatile scent signature associated with CLAs-infection settles from the canopy and simultaneously emanates from root infections pooling at the base of the tree. The detector dog interrogates the tree holistically by alerting in seconds on the scent signature regardless of its origin (i.e., a single leaf, root, stem or the entire tree if systemically infected). Conversely, other detection technologies, like PCR, are reliant on selecting and processing a small amount of tissue from large trees and often miss incipient infections because infected tissue is so rare in newly infected trees. Early detection via dogs is devoid of these sampling issues. Therefore, it is difficult to confirm CLAs detections by dogs using currently available molecular or chemical detection methods. Dogs have been tested in hot and cold temperatures and with wind speeds up to 20 MPH with no perceptible degradation in detection.

Human scouts require several minutes per tree to visually examine it for symptoms, then they must collect tissue which must be transported to a diagnostic lab for processing and analysis, which is time consuming and labor-intensive. Whereas, in a residential environment dogs can assess all trees in even large yards in a couple of minutes. The major limitation to the number of trees a dog can assess per day is access to these residential properties and the time required to relocate from property to property. In commercial groves a team of two dogs and one handler can survey a 10 acre planting (~1500 trees) in 1-2 hours depending on the number

Canine checking trees at Lindcove Research and Extension Center, Exeter, CA

The canines provide a significant opportunity to be used as an Early Detection Technology (EDT) in California. In a field study using potted citrus in Florida, dogs could detect CLAs in some of the trees as early
