

Plant Community Response to the Angora Fire: The Effects of Fire Severity on Diversity and Tree Regeneration

**JONAH WEEKS
MASTERS STUDENT
SAFFORD LAB
GRADUATE GROUP IN ECOLOGY
UNIVERSITY OF CALIFORNIA, DAVIS**

Background

- These forest types were historically characterized by frequent low severity (5-25 FRI)
 - Increased potential species pool at low-moderate at these severities
 - Pines seedlings benefit from this disturbance regime
- Time since fire is an important variable: usually just see a snap-shot at one time point

Community Changes Over Time

Moderate Severity

thinned pre-fire

2008

2009

2010

2011

2016

Objectives

- Effect of fire severity on:
 - Plant species richness over time
 - Natural tree regeneration
- Hypothesis: lower fire severity → increased species richness & regeneration of pine species

Fire Severity Classes

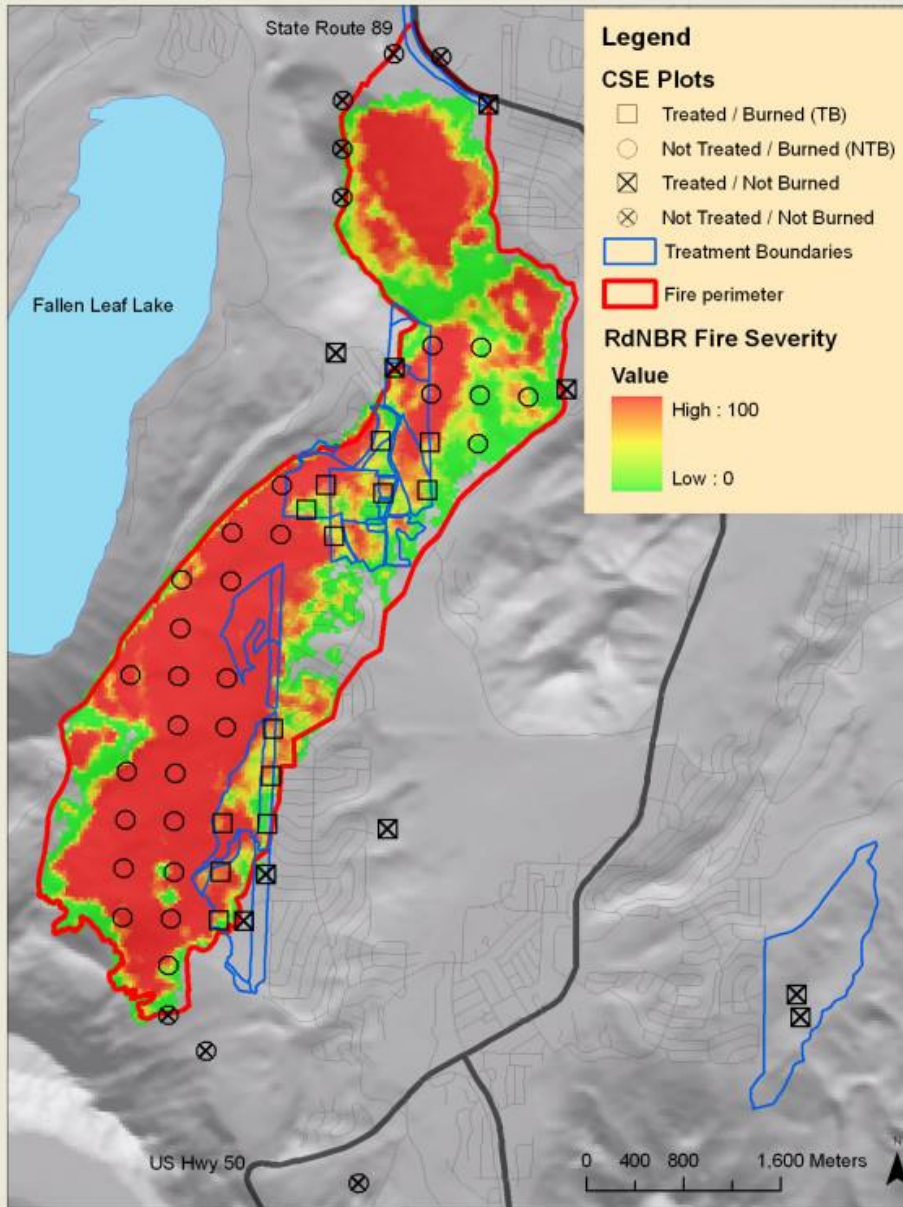

Unburned

Low: < 50%
overstory mortality

Moderate: 50-75%
overstory mortality

High: 75-90%
overstory mortality

Very High: > 90%
overstory mortality

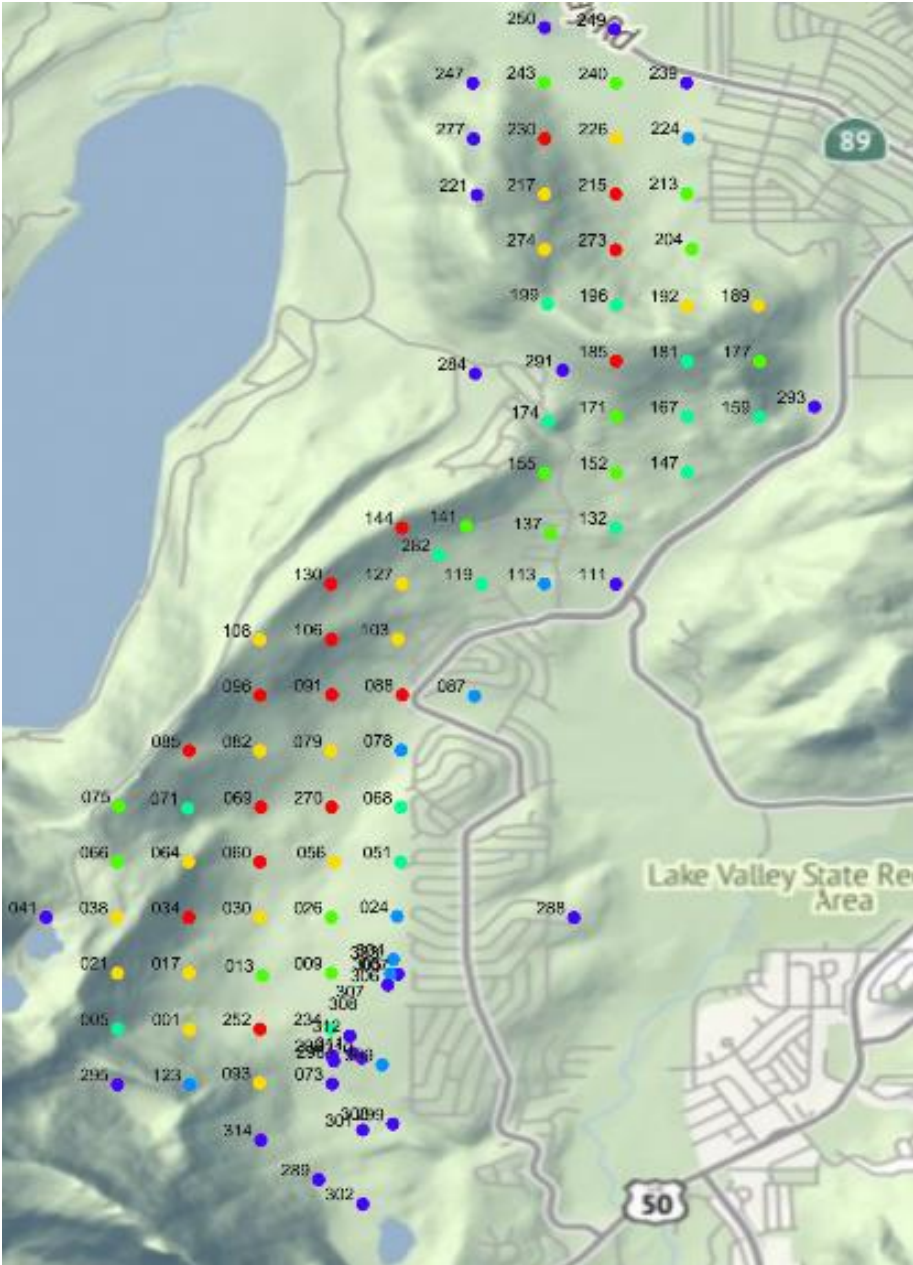

Fire severity classes: 1 year after fire

Fire severity classes 9 years after fire

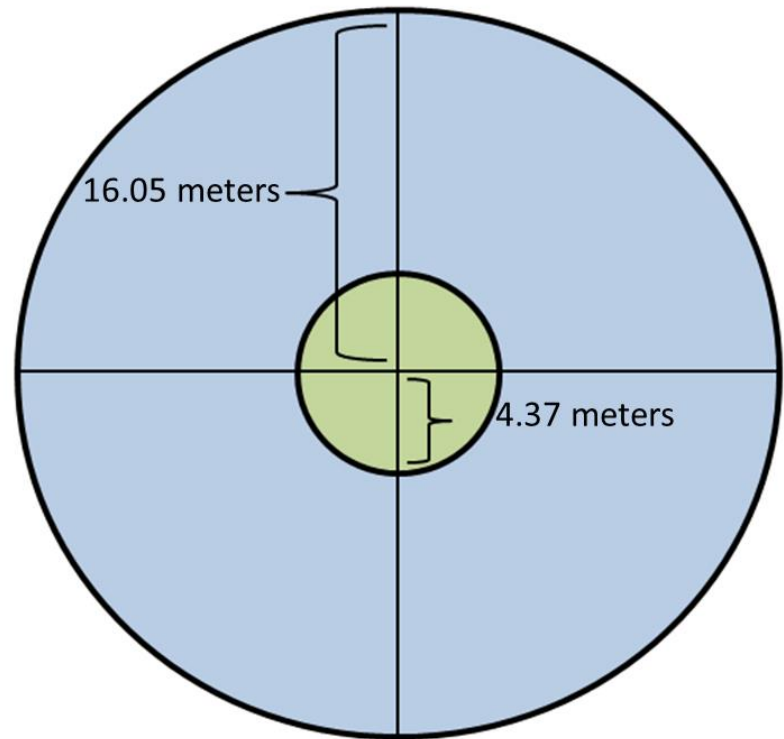

CSE Plot Locations

Protocol

- Species Composition plots:
 - All species cataloged along with %cover
 - (809m² area)
- Tree Regeneration plots
 - Age and species for each seedling
 - Height and last year's growth recorded for tallest individual of each species
 - (60m² area)

Species Richness Results

- Species richness at the plot scale over time
- Overall species richness for each fire severity class over time

Average Plot Species Richness

Overall Species Richness

Conifer Regeneration Results

- 2016 only
- Divided seedlings into shade tolerant and shade intolerant species
 - Presence and absence of these two categories
 - Medians across fire severity classes

Shade Tolerant vs Shade Tolerant Tree Species

Shade Intolerant Species:

Jeffery Pine

Lodgepole Pine

Sugar Pine

Shade Tolerant Species

White Fir

Red Fir

Incense Cedar

Percentage of Plots Containing Shade Tolerant seedlings

Percentage of Plots Containing Shade Intolerant Seedlings

Percentage of Plots with No Seedlings

Median Seedlings per Acre Across Fire Severity Class

Median Shade Tolerant Seedlings per Acre Across Fire Severity Class

Median Shade Intolerant Seedlings per Acre Across Fire Severity Class

Natural Regeneration continued

- Overall averaged seedlings/acre (all species and fire severities combined)
 - Means
 - ✦ Including unburned plots: 716 seedlings/acre
 - ✦ Including only burned plots: 580 seedlings/acre
 - Medians
 - ✦ Including unburned plots: 67 seedlings/acre
 - ✦ Including only burned plots: 67 seedlings/acre
- Overall plots with no natural regeneration
 - Including unburned plots -25%
 - Including only burned plots – 28%
- Total percentages of seedlings
 - Including unburned plots
 - ✦ 75% shade tolerant
 - ✦ 25% shade intolerant
 - Including only burned plots
 - ✦ 70% shade tolerant
 - ✦ 30% shade intolerant
- Percentage of individual species in shade tolerant and intolerant categories
 - Shade intolerant:
 - ✦ Jeffrey Pine – 67%
 - ✦ Lodgepole Pine – 23%
 - ✦ Sugar Pine – 10%
 - Shade tolerant:
 - ✦ White Fir - 64%
 - ✦ Red Fir – 26%
 - ✦ Incense Cedar – 10%

Conclusions

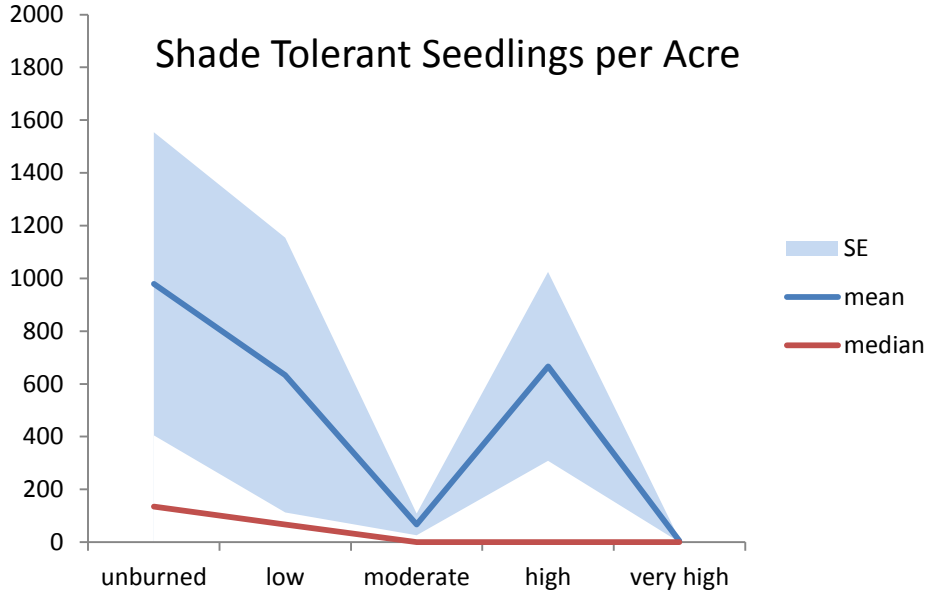

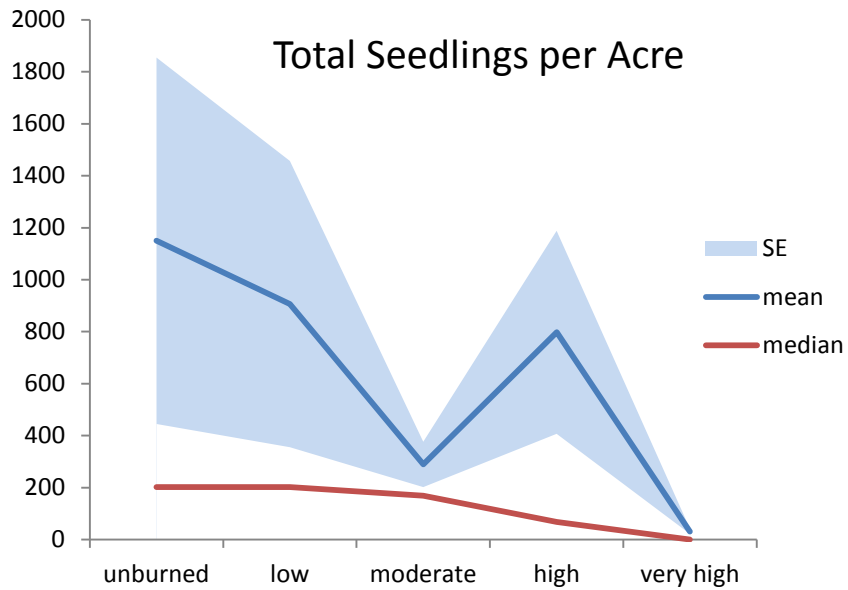

- **Important beneficial ecological responses at low and moderate fire severities.**
 - species diversity at local and regional scales are highest at these severities
 - seedling regeneration of pine species is very low outside of these fire severity classes, even after 9 years
 - Pre-fire management responsible for most of the area that burned at low-moderate severity
- **Time scale**
 - While species richness follows similar trend overtime, there is variation.
 - ✦ Can extrapolate to some degree based on one year's data
